METHOD FOR CALCULATING WING CHARACTERISTICS

BY LIFTING-LINE THEORY USING NONLINEAR

SECTION LIFT DATA

Py James C. Sivells and Robert H. Neely

#### SUMMARY

A method is presented for calculating wing characteristics by lifting-line theory using nonlinear section lift data. Material from various sources is combined with some original work into the single complete method described. Multhopp's systems of multipliers are employed to obtain the induced angle of attack directly from the spanwise lift distribution. Equations are developed for obtaining these multipliers for any even number of spanwise stations, and values are tabulated for ten stations along the semispan for asymmetrical, symmetrical, and antisymmetrical lift distributions. In order to minimize the computing time and to illustrate the procedures involved, simplified computing forms containing detailed examples are given for symmetrical lift distributions. Similar forms for asymmetrical and antisymmetrical lift distributions, although not shown, can be readily constructed in the same manner as those given. The adaptation of the method for use with linear section lift data is also illustrated. This adaptation has been found to require less computing time than most existing methods.

The wing characteristics calculated from general nonlinear section lift data have been found to agree much closer with experimental data in the region of maximum lift coefficient than those calculated on the assumption of linear section lift curves. The calculations are subject to the limitations of lifting—line theory and should not be expected to give accurate results for wings of low aspect ratio and large amounts of sweep.

## INTRODUCTION

The lifting-line theory is the best known and most readily applied theory for obtaining the spanwise lift distribution of a wing and the subsequent determination of the aerodynamic characteristics of the wing from two-dimensional airfoil data. The characteristics so determined are in fairly close agreement with experimental results for wings with small amounts of sweep and with moderate

to high values of aspect ratio; for this reason, this theory has served as the basis for a large part of present aeronautical knowledge.

The hypothesis upon which the theory is based is that a lifting wing can be replaced by a lifting line and that the incremental vortices shed along the span trail behind the wing in straight lines in the direction of the free-stream velocity. The strength of these trailing vortices is proportional to the rate of change of the lift along the span. The trailing vortices induce a velocity normal to the direction of the free-stream velocity and to the lifting line. The effective angle of attack of each section of the wing is therefore different from the geometric angle of attack by the amount of the angle (called the induced angle of attack) whose tangent is the ratio of the value of the induced velocity at the lifting line to the value of the free-stream velocity. The effective angle of attack is thus related to the lift distribution through the induced angle of attack. In addition, the effective angle of attack is related to the section lift coefficient according to two-dimensional data for the airfoil sections incorporated in the wing. Both relationships must be simultaneously satisfied in the calculation of the lift distribution of the wing.

If the section lift curves are linear, these relationships may be expressed by a single equation which can be solved analytically. In general, however, the section lift curves are not linear, particularly at high angles of attack, and analytical solutions are not feasible. The method of calculating the spanwise lift distribution using nonlinear section lift data thus becomes one of making successive approximations of the lift distribution until one is found that simultaneously satisfies the aforementioned relationships.

Such a method has been used by Wieselsberger (reference 1) for the region of maximum lift coefficient and by Boshar (reference 2) for high-subsonic speeds. Both of these writers used Tani's system of multipliers for obtaining the induced angle of attack at five stations along the semispan of the wing (reference 3). Tani, however, considered only the case of wings with symmetrical lift distributions. Multhopp (reference 4), using a somewhat different mathematical treatment from that which Tani used, derived systems of multipliers for symmetrical, antisymmetrical, and asymmetrical lift distributions for four, eight, and sixteen stations along the semispan. Multhopp's derivation, in slightly different form and nomenclature, is presented herein and tables are given for the multipliers for ten stations along the semispan (the usual number of stations considered in many reports in the United States).

S

wing area

For symmetrical distributions of wing chord and angle of attack, the multipliers for symmetrical lift distributions may be used with nonlinear or linear section lift curves. For asymmetrical distributions of angle of attack, the multipliers for asymmetrical lift distributions must be used if nonlinear section lift curves are used. If an asymmetrical distribution of angle of attack can be broken up into a symmetrical and an antisymmetrical distribution, the antisymmetrical part may be treated separately if the section lift curves can be assumed to be linear.

The purpose of the present paper is to combine the contributions of Multhopp and several other writers, together with some original work, into a single complete method of calculating the lift distributions and force and moment characteristics of wings, using nonlinear section lift data. Simplified computing forms are given for the calculation of symmetrical lift distributions and their use is illustrated by a detailed example. The adaptation of the method for use with linear section lift data is also illustrated. No forms are given for asymmetrical or antisymmetrical lift distributions inasmuch as such forms would be very similar to those given.

## THEORETICAL DEVELOPMENT OF METHOD

## Lift Distribution

The methods of Tani (reference 3) and Multhopp (reference 4) for determining the induced angle of attack are fundamentally the same, differing only in the mathematical treatment. The method presented herein is essentially the same as that given by Multhopp. In the following derivation the spanwise lift distribution is expressed as the trigonometric series

$$\frac{c_7 c}{b} = A_n \sin n\theta \tag{1}$$

as in reference 5, where  $\theta$  is defined by the relation  $\cos\theta = \frac{2y}{b}$ . It may be noted that each coefficient  $A_n$ , as used herein, is equal

to four times the corresponding coefficient in reference 5. The induced angle of attack (in degrees) at a point  $y_1$  on the lifting line is

$$\alpha_{1} = \frac{180}{\pi} \frac{p}{p} \int_{p/5}^{p/5} \frac{dx}{dx} dx \qquad (5)$$

This integral (in different nomenclature) was given by Prandtl in reference 6. If equation (1) is substituted into equation (2) and the variable is changed from y to  $\theta$ , the induced angle of attack at the general point  $\theta$  becomes, according to reference 5,

$$\alpha_{i} = \frac{180}{4\pi \sin \theta} \sum_{n} nA_{n} \sin n\theta$$
 (3)

The problem of obtaining the induced angle of attack is thus reduced to one of determining the coefficients of the trigonometric series.

The lift distribution (equation (1)) may be approximated by a finite trigonometric series of r-1 terms where, for subsequent usage, r is assumed to be even. The values of  $\frac{c_1c}{b}$  at the equally spaced points  $\theta = \frac{m\pi}{r}$  in the range  $0 < \theta < \pi$  are expressed as

$$\left(\frac{c_7 c}{b}\right)_m = \sum_{n=1}^{m-1} A_n \sin n \frac{m\pi}{r} \tag{4}$$

where  $m=1, 2, 3, \ldots, r-1$ . Conversely, if the values of  $\frac{c_1c}{b}$  are known at each point the coefficients  $A_n$  of the finite series may be found by harmonic analysis as

$$A_{n} = \frac{2}{r} \sum_{m=1}^{r-1} \frac{\binom{c_{1}c}{b}}{m} \sin n \frac{m\pi}{r}$$
 (5)

If equation (5) is substituted in equation (3), a double summation is obtained for the induced angle of attack as

$$\alpha_{1}(\theta) = \frac{180}{4\pi \sin \theta} \left( \sum_{n=1}^{r-1} n \sin n\theta \right) \left[ \frac{2}{r} \sum_{m=1}^{r-1} \left( \frac{c_{7}c}{b} \right)_{m} \sin n \frac{m\pi}{r} \right]$$

$$= \frac{180}{4\pi \sin \theta} \sum_{m=1}^{r-1} \left( \frac{c_{7}c}{b} \right)_{m} \sum_{n=1}^{r-1} n \left[ \cos n \left( \theta - \frac{m\pi}{r} \right) - \cos n \left( \theta + \frac{m\pi}{r} \right) \right]$$

If the induced angle of attack is to be determined at the same points  $\theta$  at which the load distribution is known, that is, at the points  $\theta = \frac{k\pi}{r}$ , then

$$\alpha_{1k} = \frac{180}{4\pi r \sin \frac{k\pi}{r}} \sum_{m=1}^{r-1} \left(\frac{c_7 c}{b}\right)_m \sum_{n=1}^{r-1} n \left[\cos n \frac{(k-m)\pi}{r} - \cos n \frac{(k+m)\pi}{r}\right]$$

$$=\sum_{m=1}^{r-1} \left(\frac{c_1 c}{b}\right)_m \beta_{mk} \tag{6}$$

where

$$\beta_{mk} = \frac{180}{4\pi r \sin \frac{k\pi}{r}} \sum_{n=1}^{r-1} n \left[ \cos n \frac{(k-m)\pi}{r} - \cos n \frac{(k+m)\pi}{r} \right]$$
 (7)

It can be shown that, if  $\cos \phi \neq 1$ ,

$$\sum_{n=1}^{r-1} n \cos n\emptyset = \frac{r \cos (r-1)\emptyset - (r-1) \cos r\emptyset - 1}{2(1-\cos \emptyset)}$$

If  $\phi = 0$ , a numerical series is obtained

$$\sum_{n=1}^{r-1} n = \frac{r(r-1)}{2}$$

By use of these relationships in equation (7) it is found that, when  $k \pm m$  is odd

$$\beta_{mk} = \frac{180}{4\pi r \sin\frac{k\pi}{r}} \left[ \frac{1}{1 - \cos\frac{(k+m)\pi}{r}} - \frac{1}{1 - \cos\frac{(k-m)\pi}{r}} \right]$$
(8a)

when k = m

$$\beta_{\text{mk}} = \frac{180r}{8\pi \sin \frac{k\pi}{r}} \tag{8b}$$

and when  $k \pm m$  is even and  $k \neq m$ 

$$\beta_{mk} = 0 \tag{8c}$$

For a symmetrical lift distribution

$$\left(\frac{c_{lc}}{b}\right)_{m} = \left(\frac{c_{lc}}{b}\right)_{r-m}$$

and

$$\alpha_{ik} = \alpha_{ir-k}$$

so that the summation for  $\alpha_{1k}$  needs to be made only from 1 to r/2

f

$$\alpha_{1k} = \sum_{m=1}^{r/2} \left(\frac{c_1 c}{b}\right)_m \lambda_{mk}$$
 (9)

where, when k ± m is odd

$$\lambda_{mk} = \beta_{mk} + \beta_{r-m,k}$$
 (for  $m \neq r/2$ )

$$= \frac{180}{2\pi r \sin\frac{k\pi}{r}} \begin{bmatrix} \cot\frac{(k+m)\pi}{r} & \cot\frac{(k-m)\pi}{r} \\ \sin\frac{(k+m)\pi}{r} & \sin\frac{(k-m)\pi}{r} \end{bmatrix}$$
(10a)

$$\lambda_{mk} = \beta_{mk} \quad (\text{for } m = r/2)$$

$$= -\frac{180}{\pi r(\cos \frac{2k\pi}{r} + 1)}$$
(10b)

when k = m

$$\lambda_{mk} = \beta_{mk}$$

$$= \frac{180r}{8\pi \sin \frac{k\pi}{r}}$$
(10c)

and when  $k \pm m$  is even and  $k \neq m$ 

$$\lambda_{mk} = 0 \tag{10d}$$

For an antisymmetrical lift distribution

$$\left(\frac{c_{1}c}{b}\right)_{m} = -\left(\frac{c_{1}c}{b}\right)_{r-m}$$

and

$$\alpha_{i_k} = -\alpha_{i_{r-k}}$$

In this case the summation for  $\alpha_{1k}$  needs to be made only from 1 to  $\left(\frac{r}{2}-1\right)$  since  $\left(\frac{c_1c}{b}\right)_{r/2}=0$ ; then

$$\alpha_{i_k} = \sum_{m=1}^{r} \left(\frac{c_l c}{b}\right)_m \gamma_{mk}$$
 (11)

where, when k ± m is odd

$$\gamma_{mk} = \beta_{mk} - \beta_{r-m,k}$$

$$= \frac{180}{2\pi r} \left[ \frac{1}{\sin^2 \frac{(k+m)\pi}{r}} - \frac{1}{\sin^2 \frac{(k-m)\pi}{r}} \right]$$
 (12a)

when k = m,

$$\gamma_{mk} = \beta_{mk}$$

$$= \frac{180r}{8\pi \sin \frac{k\pi}{r}}$$
(12b)

and when  $k \pm m$  is even and  $k \neq m$ 

$$\gamma_{\rm mk} = 0 \tag{12c}$$

Multipliers can thus be calculated so that the induced angle may be readily obtained by multiplying the known values of  $\frac{c_1c}{b}$  by the appropriate multipliers and adding the resulting products.

The multipliers are independent of the aspect ratio and taper ratio of the wing. Tables I and II present values of  $\beta_{mk}$ , and  $\lambda_{mk}$  and  $\gamma_{mk}$ , respectively, for r=20. Similar tables for  $\frac{4\pi}{180}\lambda_{mk}$  and  $\frac{4\pi}{180}\gamma_{mk}$  are given in references 7 and 8, respectively, but no derivation is given therein. Tables for  $\frac{2\pi}{180}\beta_{mk}$ ,  $\frac{2\pi}{180}\lambda_{mk}$ , and  $\frac{2\pi}{180}\gamma_{mk}$  are given in reference 4 for values of r=8, 16, and 32. An inspection of tables I and II shows that positive values occur only on the diagonal from upper left to lower right and that almost half of the values are equal to zero. The multipliers  $\beta_{mk}$  and  $\lambda_{mk}$  may be used with either nonlinear or linear section lift data whereas the multipliers for  $\gamma_{mk}$  may be used only with linear section lift data.

The method of determining the lift distribution becomes one of successive approximations. For a given geometric angle of attack, a distribution of  $c_l$  is assumed from which the load distribution  $\frac{c_l c}{b}$  is obtained. The induced angle of attack is then determined by equation (6), (9), or (11) through the use of the appropriate multipliers and subtracted from the geometric angle of attack to give the effective angle of attack at each spanwise station. From section data for the appropriate airfoil section and local Reynolds number, values of  $c_l$  are read which correspond to the effective angle of attack of each section. If these values of  $c_l$  do not agree with those originally assumed, a second assumption is made for  $c_l$  and the process is repeated. Further assumptions are made until the assumed values of  $c_l$  are in agreement with those obtained from the section data.

#### Wing Characteristics

Once the lift distribution of a wing has been determined, the main part of the problem of calculating the wing characteristics is completed. The induced-drag and induced-yawing-moment coefficients are entirely dependent upon the lift distribution and it is assumed that the section profile-drag and pitching-moment coefficients are the same functions of the lift coefficient at each section of the wing as those determined in two-dimensional tests.

The calculation of each of the wing coefficients involves a spanwise integration of the distribution of a particular. function  $f\left(\frac{2y}{b}\right)$ . This integration can be performed numerically through the use of additional sets of multipliers which are found in the following manner.

$$f\left(\frac{2y}{b}\right) = f(\cos \theta) = A_n \sin n\theta$$

then

$$\int_{-1}^{1} f\left(\frac{2y}{b}\right) d\left(\frac{2y}{b}\right) = \int_{0}^{\pi} \left(\sum A_{n} \sin n\theta\right) \sin \theta d\theta$$

Since the values of  $f\left(\frac{2y}{b}\right)$  are determined at the points  $\theta = \frac{m\pi}{r}$ ,  $A_1$  can be found by harmonic analysis as in equation (5)

$$A_{1} = \frac{2}{r} \sum_{m=1}^{r-1} f\left(\frac{2y}{b}\right)_{m} \sin \frac{m\pi}{r}$$

Therefore

$$\int_{-1}^{1} f\left(\frac{2y}{b}\right) d\left(\frac{2y}{b}\right) = \frac{\pi}{r} \sum_{m=1}^{r-1} f\left(\frac{2y}{b}\right)_{m} \sin \frac{m\pi}{r}$$

$$= 2 \sum_{m=1}^{r-1} f\left(\frac{2y}{b}\right)_m \eta_m$$
 (13a)

where

$$\eta_{\rm m} = \frac{\pi}{2r} \sin \frac{m\pi}{r}$$

If the distribution is symmetrical,  $f\left(\frac{2y}{b}\right)_m = f\left(\frac{2y}{b}\right)_{r-m}$  and

$$\int_{-1}^{1} f\left(\frac{2y}{b}\right) d\left(\frac{2y}{b}\right) = 2 \sum_{m=1}^{r/2} f\left(\frac{2y}{b}\right)_{m} \eta_{ms}$$
 (13b)

where

$$\eta_{\text{ms}} = 2\eta_{\text{m}} \qquad \left(m \neq \frac{r}{2}\right)$$

$$\eta_{ms} = \eta_m \qquad \left(m = \frac{r}{2}\right)$$

The moment of the distribution  $f\left(\frac{2y}{b}\right)$  can be found in a similar manner.

$$\int_{-1}^{1} f\left(\frac{2y}{b}\right) \left(\frac{2y}{b}\right) d\left(\frac{2y}{b}\right) = \int_{0}^{\pi} \left(\sum A_{n} \sin n\theta\right) \sin \theta \cos \theta d\theta$$

$$= \frac{\pi}{4} A_2$$

$$= \frac{\pi}{2r} \sum_{m=1}^{r-1} f\left(\frac{2y}{b}\right)_m \sin \frac{2m\pi}{r}$$

$$= 4 \sum_{m=1}^{r-1} f\left(\frac{2y}{b}\right)_m \sigma_m$$
 (14a)

where

$$\sigma_{\rm m} = \frac{\pi}{8r} \sin \frac{2m\pi}{r}$$

If the distribution is antisymmetrical,  $f\left(\frac{2y}{b}\right)_m = -f\left(\frac{2y}{b}\right)_{r-m}$ 

$$\int_{-1}^{1} f\left(\frac{2y}{b}\right) \left(\frac{2y}{b}\right) d\left(\frac{2y}{b}\right) = 4 \sum_{m=1}^{\frac{r}{2}-1} f\left(\frac{2y}{b}\right)_{m} \sigma_{ma}.$$
 (14b)

where

$$\sigma_{\text{ma}} = 2\sigma_{\text{m}}$$

Values of  $\eta_m$ ,  $\eta_{ms}$ ,  $\sigma_m$ , and  $\sigma_{ma}$  are given in table III for r=20.

Wing lift coefficient. The wing lift coefficient is obtained by means of a spanwise integration of the lift distribution,

$$C_{L} = \frac{1}{S} \int_{0-b/2}^{b/2} c_{l} c dy$$

$$= \underbrace{A}_{2} \int_{-1}^{1} \frac{c_{1}c}{b} d\left(\frac{2y}{b}\right)$$

If the lift distribution is asymmetrical

$$C_{L} = A \sum_{m=1}^{r-1} \left(\frac{c_{1}c}{b}\right)_{m} \eta_{m}$$
 (15a)

If the lift distribution is symmetrical

$$C_{L} = A \sum_{m=1}^{r/2} \left(\frac{c_{1}c}{b}\right)_{m} \eta_{ms}$$
 (15b)

Induced-drag coefficient. The section induced-drag coefficient is equal to the product of the section lift coefficient and the induced angle of attack in radians,

$$c_{d_1} = \frac{\pi c_2 \alpha_1}{180}$$

The wing induced-drag coefficient is obtained by means of a spanwise integration of the section induced-drag coefficient multiplied by the local chord;

$$c_{D_1} = \frac{1}{S} \int_{-b/2}^{b/2} \frac{\pi c_1 c \alpha_1}{180} dy$$

$$= \frac{A}{2} \int_{-1}^{1} \frac{c_1 c}{b} \frac{\pi \alpha_1}{180} d\left(\frac{2y}{b}\right)$$

For asymmetrical lift distributions

$$C_{D_1} = \frac{\pi A}{180} \sum_{m=1}^{r-1} \left( \frac{c_1 c}{b} \alpha_1 \right)_m \eta_m$$
 (16a)

For symmetrical lift distributions

$$c_{D_{i}} = \frac{\pi A}{180} \sum_{m=1}^{r/2} \left(\frac{c_{1}c}{b} \alpha_{i}\right)_{m} \eta_{ms}$$
 (16b)

Profile-drag coefficient. The section profile-drag coefficient can be obtained from section data for the appropriate airfoil section and local Reynolds number. For each spanwise station the profile-drag coefficient is read at the section lift coefficient previously determined. The wing profile-drag coefficient is then obtained by means of a spanwise integration of the section profile-drag coefficient multiplied by the local chord:

$$c_{D_0} = \frac{1}{5} \int_{-b/2}^{b/2} c_{d_0} c dy$$

$$= \frac{1}{2} \int_{-1}^{1} c_{d_0} \frac{c}{c} d\left(\frac{2y}{b}\right)$$

For asymmetrical lift distributions

$$C_{D_O} = \sum_{m=1}^{r-1} \left( c_{d_O \overline{c}} \right)_m \eta_m$$
 (17a)

or for symmetrical lift distributions

$$C_{D_{O}} = \sum_{m=1}^{r/2} \left( c_{d_{O_{\overline{C}}}} \right)_{m} \eta_{ms}$$
 (17b)

Pitching-moment coefficient.— The section pitching-moment coefficient about its quarter-chord point can be obtained from section data for the appropriate airfoil section and local Reynolds number. For each spanwise station the pitching-moment coefficient is read at the section lift coefficient previously determined and then transferred to the wing reference point by the equation

$$c_{m} = c_{m_{c}/4} - \frac{x}{c} \left[ c_{l} \cos (\alpha_{s} - \alpha_{i}) + c_{d_{o}} \sin (\alpha_{s} - \alpha_{i}) \right]$$
$$- \frac{z}{c} \left[ c_{l} \sin (\alpha_{s} - \alpha_{i}) - c_{d_{o}} \cos (\alpha_{s} - \alpha_{i}) \right]$$
(18)

where x and z are measured from the wing reference point to the quarter-chord point of the section under consideration and upward and backward forces and distances are taken as positive. The section pitching-moment coefficient about its aerodynamic center may be used instead of  $c_{m_{\rm C}/4}$ , in which case x and z are measured to the section aerodynamic center. The term  $c_{\rm d_O}$  sin  $(c_{\rm S}-c_{\rm i})$  may usually be neglected. The wing pitching-moment coefficient is obtained by the spanwise integration

$$c_{\rm m} = \frac{1}{8c^2} \int_{-b/2}^{b/2} c_{\rm m} c^2 dy$$

$$= \frac{1}{2} \int_{-1}^{1} \left( \frac{c_m c^2}{\overline{c} c^t} \right) d\left( \frac{2y}{b} \right)$$

For asymmetrical lift distributions

$$C_{\rm m} = \sum_{\rm m=1}^{\rm r-1} \left(\frac{c_{\rm m}c^2}{c_{\rm c}!}\right)_{\rm m} \eta_{\rm m} \tag{19a}$$

For symmetrical lift distributions

$$C_{\rm m} = \sum_{\rm m=1}^{\rm r/2} \left(\frac{c_{\rm m}c^2}{c_{\rm c}!}\right)_{\rm m} \eta_{\rm ms} \tag{19b}$$

Rolling-moment coefficient. The rolling-moment coefficient is obtained by means of a spanwise integration

$$C_{l} = -\frac{1}{\text{Sb}} \int_{-b/2}^{b/2} c_{l} c_{y} dy$$

$$= -\frac{A}{4} \int_{-1}^{1} \frac{c_{l} c}{b} \frac{2y}{b} d\left(\frac{2y}{b}\right)$$

$$= -A \sum_{m=1}^{r-1} \left(\frac{c_{l} c}{b}\right)_{m} \sigma_{m} \qquad (20a)$$

For an antisymmetrical lift distribution

$$C_{\zeta} = -A \sum_{m=1}^{\frac{r}{2}-1} \left(\frac{c_{\zeta}c}{b}\right)_{m} \sigma_{m_{\Omega}}$$
 (20b)

Induced—yawing—moment coefficient.— The induced—yawing—moment coefficient is due to the moment of the induced—drag distribution

$$c_{n_{\underline{i}}} = \frac{1}{\text{Sb}} \int_{-b/2}^{b/2} \frac{\pi c_{1} c \alpha_{\underline{i}}}{180} y \, dy$$

$$= \frac{A}{4} \int_{-1}^{1} \frac{c_{1} c}{b} \frac{\pi \alpha_{\underline{i}}}{180} \frac{2y}{b} \, d\left(\frac{2y}{b}\right)$$

$$= \frac{\pi A}{180} \sum_{\underline{m}=1}^{p-1} \left(\frac{c_{1} c}{b} \alpha_{\underline{i}}\right)_{\underline{m}} \sigma_{\underline{m}} \qquad (21)$$

The induced—yawing—moment coefficient for an antisymmetrical lift distribution is equal to zero and has little meaning inasmuch as the lift coefficient is also zero. The induced—yawing—moment coefficient is a function of the lift and rolling—moment coefficients and must be found for asymmetrical lift distributions.

<u>Profile-yawing-moment coefficient.</u>— The profile-yawing-moment coefficient is due to the moment of the profile-drag distribution.

$$C_{n_o} = \frac{1}{\text{Sb}} \int_{-b/2}^{b/2} c_{d_o} cy \, dy$$

$$= \frac{1}{4} \int_{-1}^{1} \frac{c_{d_o} c}{\overline{c}} \frac{2y}{b} \, d\left(\frac{2y}{b}\right)$$

$$= \sum_{m=1}^{r-1} \left(\frac{c_{d_o} c}{\overline{c}}\right)_m \sigma_m \qquad (22)$$

## APPLICATION OF METHOD USING NONLINEAR SECTION LIFT DATA

#### FOR SYMMETRICAL LIFT DISTRIBUTIONS

The method described is applied herein to a wing, the geometric characteristics of which are given in table IV. Only symmetrical lift distributions are considered hereinafter inasmuch as these are believed to be sufficient for illustrating the method of calculation. The lift, profile-drag, and pitching-moment coefficients for the various wing sections along the span were derived from unpublished airfoil data obtained in the Langley two-dimensional low-turbulence pressure tunnel. The original arrfoil data were cross-plotted against Reynolds number and thickness ratio inasmuch as both varied along the span of the wing. Sample curves are given in figures 1 and 2. From these plots the section characteristics at the various spanwise stations were determined and plotted in the conventional manner. (See fig. 3.) The edge-velocity factor E, derived in reference 9 for an elliptic wing, has been applied to the section angle of attack for each value of section lift coefficient as follows:

$$\alpha_{\Theta} = \mathbb{E} \left( \alpha_{O} - \alpha_{l_{O}} \right) + \alpha_{l_{O}}$$

### Lift Distribution

Computation of the lift distribution at an angle of attack of 3° is shown in table V. This table is designed to be used where the multiplication is done by means of a slide rule or simple calculating machine. Where calculating machines capable of performing accumulative multiplication are available, the spaces for the individual products in columns (6) to (15) may be omitted and the table made smaller. (See tables VII and VIII.) The mechanics of computing are explained in the table; however, the method for approximating the lift coefficient distribution requires some explanation. The initially assumed lift—coefficient distribution (column (3) of first division) can be taken as the distribution given by the geometric angles of attack but it is best determined by some simple method which will give a close approximation to the actual distribution. The initial distribution given in table V was approximated by

$$c_{l} = \frac{A}{A + 1.8} \left[ \frac{1}{2} + \frac{2\overline{c}}{\pi c} \sqrt{1 - \left(\frac{2y}{b}\right)^{2}} \right] c_{l(\alpha)}$$

where  $c_{l(\alpha)}$  is the lift coefficient read from the section curves for the geometric angles of attack. This equation weights the lift distribution according to the average of the chord distribution of the wing under consideration and that of an elliptical wing of the same aspect ratio and span. When the lift distributions at several angles of attack are to be computed and after they have been obtained for two angles, the initial assumed  $c_l$  distribution for subsequent angles can be more accurately estimated in the following manner: Values of downwash angle are first estimated by extrapolating from values for the preceding wing angles, and then, for the resulting effective angles of attack, the lift coefficients are read from the section curves.

The lift coefficients in column (18) of table V, read from section lift curves for the effective angles of attack, will usually not check the assumed values for the first approximation. In order to select assumed values for subsequent approximations, the following simple method has been found to yield satisfactory results. An incremental value of lift coefficient  $\Delta c_{lm}$  is obtained according to the relation (numbers in parenthesis are columns in table V):

$$\Delta c_{lm} = \frac{[(18) - (3)]_{m-1} + 3[(18) - (3)]_m + [(18) - (3)]_{m+1}}{\kappa}$$

where K has the following values at the spanwise stations

and (18) - (3)<sub>m</sub> is the difference between the check and assumed values for the mth spanwise station. The incremental values so determined are added to the assumed values in order to obtain new assumed values to be used in the next approximation. This method has been found in practice to make the check and assumed values converge in about three approximations if the first approximation is not too much in error.

## Wing Coefficients

Computations of the wing lift, profile-drag, induced-drag, and pitching-moment coefficients are shown in table VI. Since the lateral axis through the wing reference point contains the quarter-chord points of each section, the x and z distances in equation (18) are zero, and the pitching-moment coefficient of the wing is determined solely by the values of  $c_{m_{\rm C}/h}$ .

#### APPLICATION OF METHOD USING LINEAR SECTION LIFT DATA

#### FOR SYMMETRICAL LIFT DISTRIBUTIONS

Although the method described herein was developed particularly for use with nonlinear section lift data, it is readily adaptable for use with linear section lift data with a resulting reduction in computing time as compared with most existing methods. When the section lift curves can be assumed linear, it is usually convenient to divide any symmetrical lift distribution (as in reference 10)

into two parts — the additional lift distribution due to angle of attack changes and the basic lift distribution due to aerodynamic twist. The calculation of these lift distributions is illustrated in tables VII to X for the wing, the geometric characteristics of which were given in table IV.

It should be noted that tables VII and VIII are essentially the same as table V but are designed primarily for use with calculating machines capable of performing accumulative multiplication. If such machines are not available, these tables may be constructed similar to table V to allow spaces for writing the individual products.

### Lift Characteristics

Two lift distributions are required for the determination of the additional and basic lift distributions. The first one is obtained in table VII for a constant angle of attack  $\alpha_{a_8}$  ( $\epsilon$ ' = 0) and the second one in table VIII for the angle of attack distribution due to the aerodynamic twist ( $\alpha_{a_8}$  = 0). The check values of  $\frac{c_1c}{b}$  (column (18)) are obtained by multiplying the effective angle of attack  $\alpha_e$  by  $\frac{a_0c}{b}$ . The final approximations are entered in table IX as  $(\frac{c_1c}{b})$  and  $(\frac{c_1c}{b})$ .

The  $\binom{c_1c}{b}_{(\alpha_{a_s})}$  distribution is the additional lift distribution corresponding to a wing lift coefficient  $c_{L(\alpha_{a_s})}$  determined in table IX through the use of the multipliers  $\eta_{ms}$ . It is usually convenient to use the additional lift distribution  $\frac{c_{lal}c}{b}$  corresponding to a wing lift coefficient of unity. This distribution is found by dividing the values of  $\binom{c_lc}{b}_{(\alpha_{a_s})}$  by  $c_{L(\alpha_{a_s})}$ .

The  $\left(\frac{c_7c}{b}\right)_{(\epsilon_t')}$  distribution is a combination of the basic lift distribution and an additional lift distribution corresponding to a wing lift coefficient  $\frac{C_L(\epsilon_t')}{b}$  also determined in table IX. The basic lift distribution  $\frac{c_1b^c}{b}$  is then determined by subtracting the additional lift distribution  $\frac{c_1al^c}{b}$   $\frac{c_L(\epsilon_t')}{b}$  from  $\frac{c_1c}{b}(\epsilon_t')$ .

Inasmuch as the wing lift curve is assumed to be linear, it is defined by its slope and angle of attack for zero lift which are also found in table IX. The maximum wing lift coefficient is estimated according to the method of reference 10 which is illustrated in figure 4. The maximum lift coefficient is considered to be the wing lift coefficient at which some section of the wing becomes the first to reach its maximum lift, that is,  $c_{lb} + c_{L} c_{lal} = c_{lmax}$ . This value of  $c_{L}$  is most conveniently determined by finding the minimum value of  $c_{lal}$  along the span as illustrated in table IX.

## Induced-Drag Coefficient

The section induced-drag coefficient is equal to the product of the section lift coefficient and the induced angle of attack in radians. The lift distribution for any wing lift coefficient is

$$\frac{c_1 c}{b} = \frac{c_{lal} c}{b} C_L + \frac{c_{lb} c}{b}$$
 (23)

The corresponding induced angle of attack distribution may be written as

$$\alpha_{\underline{i}} = \alpha_{\underline{i}_{\underline{a}}}, C_{\underline{L}} + \alpha_{\underline{i}_{\underline{b}}}$$
 (24)

The values of  $\alpha_{1a1}$  and  $\alpha_{1b}$  are determined in table X in the same manner as  $\frac{c_{la1}c}{b}$  and  $\frac{c_{lb}c}{b}$  in table IX. The induced-drag distribution is therefore

$$\frac{c_{\underline{d_1}c}}{b} = \frac{c_7c}{b} \frac{\alpha_1}{57.3}$$

or

$$\frac{c_{\underline{d}_{\underline{1}}}c}{b} = \frac{c_{\underline{d}_{\underline{1}}\underline{a}_{\underline{1}}}c}{b} c_{\underline{L}}^2 + \frac{c_{\underline{d}_{\underline{1}}\underline{a}_{\underline{1}}}c}{b} c_{\underline{L}} + \frac{c_{\underline{d}_{\underline{1}}\underline{b}}c}{b}$$
(25)

where

$$\frac{c_{d_{\underline{1}a\underline{1}}}c}{b} = \frac{c_{l_{\underline{a}\underline{1}}}c}{b} \frac{\alpha_{\underline{1}a\underline{1}}}{57.3}$$
 (26)

$$\frac{c_{\bar{d}ialb}^c}{b} = \frac{c_{lal}^c}{b} \frac{\alpha_{ib}}{57.3} + \frac{c_{lb}^c}{b} \frac{\alpha_{ial}}{57.3}$$
(27)

and

$$\frac{c_{d_{1b}}c}{b} = \frac{c_{lb}c}{b} \frac{\alpha_{lb}}{57.3} \tag{28}$$

The calculation of each of these induced-drag distributions is illustrated in table X together with the numerical integration of each distribution to obtain the wing induced-drag coefficient.

Profile-Drag and Pitching-Moment Coefficients

The profile-drag and pitching-moment coefficients for the wing depend directly upon the section data and therefore their calculation is the same whether linear or nonlinear section lift data are used. For the linear case the section lift coefficient is

for any wing coefficient  $C_L$ . By use of this value for  $c_l$  the profile-drag and pitching-moment coefficients are found as in table VI.

#### DISCUSSION

The characteristics of three wings with symmetrical lift distributions have been calculated by use of both nonlinear and linear section lift data and are presented in figure 5 together with experimental results. These data were taken from reference 11. The lift curves calculated by use of nonlinear section lift data are in close agreement with the experimental results over the entire range of lift coefficients whereas those calculated by use of linear section lift data are in agreement only over the linear portions of the curves as would be expected.

It must be remembered that the methods presented are subject to the limitations of lifting—line theory upon which the methods are based; therefore, the close agreement shown in figure 5 should not be expected for wings of low aspect ratio or large sweep. The use of the edge—velocity factor more or less compensates for some of the effects of aspect ratio and, in fact, appears to over compensate at the larger values of aspect ratio as shown in figure 5.

Additional comparisons of calculated and experimental data are given in reference 11 for wings with symmetrical lift distributions, but very little comparable data are available for wings with asymmetrical lift distributions. Such data are very desirable in order to determine the reliability with which calculated data may be used to predict experimental wing characteristics.

For tapered wings with straight-line elements from root to construction tip  $\frac{c}{c_S} = 1 - \left(1 - \frac{c_t}{c_S}\right) \frac{2y}{b}$   $\left(\frac{\epsilon}{\epsilon_t}\right)_{\text{Geom.}} = \frac{c_t}{c_S} \frac{2y/b}{c/c_S}$ 

(Alter values of c/c<sub>s</sub> near tip to allow for rounding)

(Use value of c/c<sub>s</sub> before rounding tip)
